TL;DR (Too Long; Didn't Read) To calculate the amount of heat released in a chemical reaction, use the equation $Q = mc \Delta T$, where Q is the heat energy transferred (in joules), m is the mass of the liquid being heated (in grams), c is the specific heat capacity of the liquid (joule per gram degrees Celsius) and ΔT is the change in temperature of the liquid (degrees Celsius).

Figure 8a-2: The three diagrams above illustrate the distinct arrangement patterns of water molecules as they change their physical state from ice to water to gas. Frozen water molecules arrange themselves in a particular highly organized rigid geometric pattern that causes the mass of water to expand and

ICHMT provides a unique apolitical forum for the world's leading heat and mass transfer scientists and engineers. Our mission is to pursue excellence and foster the international exchange of science and engineering in all branches of heat and mass transfer through symposia, publications, and promotion of research, education and exchange of personnel for the benefit of people everywhere.

Mass transfer is the net movement of mass from one location, usually meaning stream, phase, fraction or component, to another. Mass transfer occurs in many processes, such as absorption, evaporation, drying, precipitation, membrane filtration, and distillation. Mass transfer is used by different scientific disciplines for different processes and mechanisms.

Heat capacity is the amount of energy (heat) needed to increase temperature of a substance by one degree. It reflects the capacity of the substance to retain heat. As defined, heat capacity has only a limited application since it is extensive property i.e. depends on mass of the substance. In Physics, specific heat ...
